

LU01a - Creating a component

Define the function

With `function Product() { }` you define a JavaScript function with the name Product. This is also going to be our components name

```
function Product() {  
  
}
```

Return markup

Each component must return a value. We create a `return()` using JSX markup. This is a special markup language made for React that allows HTML to be written in JS as well.

```
function Product() {  
  return (  
    <div>  
        
      <h2>Product Name</h2>  
      <p>Product Description</p>  
      <p>$20</p>  
    </div>  
  );  
}
```

Export the component

Now we have a component. But if we want to use it in other files, we have to export the function. To export a component, you have to add the keywords „export default“ in front of the function declaration. That way, the function is marked to be exported. Now, you can include the file in an another file to use this component.

Product.js

```
export default function Product() {  
  return (  
    <div>  
        
    </div>  
  );  
}
```

ProductsList.js

```
import Product from './Product.js';

export default function ProductsList() {
  return (
    <div>
      <h1>Our Products</h1>
      <Product />
      <Product />
      <Product />
      <Product />
    </div>
  );
}
```
