

LU03a - Concept of a RDB

A Relational Database (RDB) is a structured method for storing and organizing data. The core idea is to represent data as related tables.

Key components

- **Tables:** A collection of related data organized into rows (records) and columns (fields). Each row represents a unique entity, and columns contain specific attributes.
- **Records:** A single row in a table, representing a specific instance of data.
- **Fields:** A column in a table, defining the type of data stored in each row.
- **Relationships:** Connections between tables based on shared data. Common types include one-to-one, one-to-many, and many-to-many relationships.

Structure and Integrity

- **Primary Key:** A unique identifier for each record in a table.
- **Foreign Key:** A field in one table that references the primary key in another table, establishing a relationship.
- **Data Integrity:** Ensures data accuracy and consistency through constraints like:
 - Entity Integrity: Every table must have a primary key with no null values.
 - Referential Integrity: Foreign key values must match existing primary key values or be null.
 - Domain Integrity: Data values must conform to defined data types.

Advantages of RDBs

- **Data Consistency:** Enforced by relationships and constraints.
- **Data Security:** Access control mechanisms protect sensitive information.
- **Data Independence:** Changes to data structure can be made without affecting applications.
- **Efficient Data Access:** Indexing and query optimization enhance performance.

Common RDB Systems

- MySQL
 - PostgreSQL
 - Oracle Database
 - Microsoft SQL Server
-

Vocabulary

English	German
row	Zeile
column	Spalte
entity	Objekt(-Einheit)
attribute	Eigenschaft
instance	Exemplar, Beispiel
unique	einzig(-artig)
to reference to	verweisen auf
to establish	errichten, herstellen
consistency	Widerspruchsfreiheit, Übereinstimmung
constraint	Auflage, Bedingung
to enhance	verbessern, aufwerten
