4. [W3Schools | Constraints | FOREIGN KEY](#)
5. [W3Schools | Constraints | NOT NULL](#)
6. [W3Schools | Constraints | UNIQUE](#)

Learning Objectives

1. Discuss what database CONSTRAINTS are and for they are needed
2. Explain the four most important CONSTRAINTS in database systems
3. Apply CONSTRAINTS to entity and relation tables in databases

Overview

Sources:

- [Youtube-DE | Übersicht CONSTRAINTS](#)
- [Youtube-EN | CONSTRAINT Tutorial](#)

MySQL constraints ensure data integrity, enforcing rules at the database level. CONSTRAINTS restrict the type of data that can be inserted into tables, preventing invalid entries and ensuring relationships between tables remain accurate. The most common constraints in MySQL are

1. PRIMARY KEY
2. AUTO_INCREMENT
3. NOT NULL
4. UNIQUE
5. FOREIGN KEY

Let's explore these CONSTRAINTS with their syntax and practical examples.

1. PRIMARY KEY

The Primary Key constraint uniquely identifies each record in a table. A primary key column (or a set of columns) must contain unique, non-null values. Each table can have only one primary key.

General Syntax

```
CREATE TABLE table_name (  
    column_name1 datatype PRIMARY KEY,  
    column_name2 datatype
```

```
);
```

Example

In the following example, `customer_id` is the primary key, ensuring that every customer has a unique ID. It prevents any duplication of the `customer_id`.

```
CREATE TABLE customers (  
    customer_id INT PRIMARY KEY,  
    customer_name VARCHAR(50)  
);
```

2. AUTO INCREMENT

The `AUTO_INCREMENT` attribute automatically generates a unique number for new rows. It is typically used with the primary key to create unique identifiers without manual input.

General Syntax

```
CREATE TABLE table_name (  
    column_name datatype AUTO_INCREMENT,  
    PRIMARY KEY (column_name)  
);
```

Example

```
CREATE TABLE products (  
    product_id INT AUTO_INCREMENT PRIMARY KEY,  
    product_name VARCHAR(50)  
);
```

Here, `product_id` automatically increments each time a new row is inserted, ensuring a unique ID for every product.

3. NOT NULL

The `NOT NULL` constraint ensures that a column cannot contain a `NULL` value. It is used when the column must always have a value.

General Syntax

```
CREATE TABLE table_name (  
    column_name datatype NOT NULL  
);
```

Example

```
CREATE TABLE employees (  

```

```
employee_id INT PRIMARY KEY,  
employee_name VARCHAR(50) NOT NULL  
);
```

In this example, the `employee_name` column is constrained to never contain a `NULL` value, ensuring every employee has a name.

4. UNIQUE

The `UNIQUE` constraint ensures that all values in a column (or a set of columns) are unique across the table. Unlike the primary key, a table can have multiple unique constraints.

General Syntax

```
CREATE TABLE table_name (  
    column_name datatype UNIQUE  
);
```

Example

```
CREATE TABLE users (  
    user_id INT PRIMARY KEY,  
    email VARCHAR(100) UNIQUE  
);
```

In this case, the `email` column must contain unique values. No two users can have the same email address.

5. FOREIGN KEY

The Foreign Key constraint ensures referential integrity by linking a column in one table to the primary key of another. It establishes a relationship between two tables and enforces the rule that data in the foreign key column must match an existing primary key in the referenced table.

General Syntax

```
CREATE TABLE table_name (  
    column_name1 datatype,  
    column_name2 datatype,  
    FOREIGN KEY (column_name1) REFERENCES another_table(primary_key_column)  
);
```

Example

```
CREATE TABLE orders (  
    order_id INT PRIMARY KEY,  
    customer_id INT,  
    FOREIGN KEY (customer_id) REFERENCES customers(customer_id)
```

```
);
```

In this example, `customer_id` in the `orders` table references the `customer_id` in the `customers` table. This relationship ensures that any `customer_id` in the `orders` table corresponds to an existing customer in the `customers` table.

Practical Example with Multiple Constraints

Let's create a `students` table to demonstrate multiple constraints in action.

```
CREATE TABLE students (  
  student_id INT AUTO_INCREMENT PRIMARY KEY,  
  student_name VARCHAR(50) NOT NULL,  
  email VARCHAR(100) UNIQUE,  
  class_id INT,  
  FOREIGN KEY (class_id) REFERENCES classes(class_id)  
);
```

Summary

In summary, MySQL constraints like Primary Key, Foreign Key, NOT NULL, AUTO_INCREMENT, and UNIQUE are essential for maintaining data accuracy, integrity, and consistency across a database. They enforce rules at the database level, ensuring reliable data relationships and preventing errors.

- **PRIMARY KEY** is applied to `student_id` to uniquely identify each data record in the table.
- **AUTO_INCREMENT** is applied to `student_id` to automatically generate a unique ID for each student.
- **NOT NULL** is applied to `student_name`, requiring every student to have a name.
- **UNIQUE** ensures that no two students can register with the same email.
- **FOREIGN KEY** links `class_id` to another table `classes`, maintaining the relationship between students and their class.

Why Use Constraints?

- **Data Integrity:** Constraints ensure that the data stored in the database adheres to rules, such as ensuring unique IDs or valid foreign key relationships.
- **Preventing Errors:** Constraints like NOT NULL prevent the insertion of incomplete or invalid data.
- **Automation:** **AUTO_INCREMENT** simplifies the process of assigning unique identifiers without user input.

Vocabulary

English	Deutsch
constraint	Bedingung, Beschränkung
to enforce	durchsetzen

English	Deutsch
to restrict	einschränken, beschränken
to prevent	verhindern
uniquely	eindeutig
